Homework 1

Danny Dawson

Table of contents

Link to the Github repository

❗ Due: Sun, Jan 29, 2023 @ 11:59pm

Please read the instructions carefully before submitting your assignment.

1. This assignment requires you to:
    - Upload your Quarto markdown files to a `git` repository
    - Upload a `PDF` file on Canvas
2. Don't collapse any code cells before submitting.
3. Remember to make sure all your code output is rendered properly before uploading your submission.

Please add your name to the the author information in the frontmatter before submitting your assignment.

Question 1

20 points

In this question, we will walk through the process of *forking* a `git` repository and submitting a *pull request*.

1. Navigate to the Github repository here and fork it by clicking on the icon in the top right

   Provide a sensible name for your forked repository when prompted.

2. Clone your Github repository on your local machine

```
$ git clone <<insert your repository url here>>
$ cd hw-1
```

   Alternatively, you can use Github codespaces to get started from your repository directly.

3. In order to activate the `R` environment for the homework, make sure you have `renv` installed beforehand. To activate the `renv` environment for this assignment, open an instance of the `R` console from within the directory and type

```
renv::activate()
```

   Follow the instrutions in order to make sure that `renv` is configured correctly.

4. Work on the *reminaing part* of this assignment as a `.qmd` file.

   - Create a `PDF` and `HTML` file for your output by modifying the YAML frontmatter for the Quarto `.qmd` document

5. When you're done working on your assignment, push the changes to your github repository.

6. Navigate to the original Github repository here and submit a pull request linking to your repository.

   Remember to **include your name** in the pull request information!

If you're stuck at any step along the way, you can refer to the official Github docs here

---

Question 2

30 points

Consider the following vector

```
my_vec <- c(
    "+0.07",
    "-0.07",
    "+0.25",
    "-0.84",
    "+0.32",
    "-0.24",
    "-0.97",
    "-0.36",
    "+1.76",
    "-0.36"
)
```

For the following questions, provide your answers in a code cell.

1. What data type does the vector contain?

this vector contains character strings

1. Create two new vectors called `my_vec_double` and `my_vec_int` which converts `my_vec` to Double & Integer types, respectively,

```
my_vec_double <- as.double(my_vec)

my_vec_double
```

```
[1]  0.07 -0.07  0.25 -0.84  0.32 -0.24 -0.97 -0.36  1.76 -0.36
```

```r
my_vec_int <- as.integer(my_vec)

my_vec_int
```

```
[1] 0 0 0 0 0 0 0 0 1 0
```

1. Create a new vector `my_vec_bool` which comprises of:
    - `TRUE`if an element in `my_vec_double` is ≤ 0
    - `FALSE` if an element in `my_vec_double` is ≥ 0

```r
my_vec_bool <- my_vec_double <= 0

my_vec_bool
```

```
 [1] FALSE  TRUE FALSE  TRUE FALSE  TRUE  TRUE  TRUE FALSE  TRUE
```

`How many elements of `my_vec_double` are greater than zero?`

4 elements are greater than zero

1. Sort the values of `my_vec_double` in ascending order.

```r
sort(my_vec_double)
```

```
 [1] -0.97 -0.84 -0.36 -0.36 -0.24 -0.07  0.07  0.25  0.32  1.76
```

Question 3

> 50 points

In this question we will get a better understanding of how `R` handles large data structures in memory.

1. Provide `R` code to construct the following matrices:

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 1 & 2 & 3 & 4 & 5 & \ldots & 100 \\ 1 & 4 & 9 & 16 & 25 & \ldots & 10000 \end{bmatrix}$$

> **Tip**
>
> Recall the discussion in class on how R fills in matrices

```
matrix_one <-
  matrix(c(1, 2, 3, 4, 5, 6, 7, 8, 9),
  nrow = 3,
  byrow = TRUE)

matrix_one
```

```
     [,1] [,2] [,3]
[1,]    1    2    3
[2,]    4    5    6
[3,]    7    8    9
```

```
row_one <- 1:100     #need list of numbers from 1 to 100
row_two <- row_one^2   #this squares the values of row_one

matrix_two <-
 matrix(c(row_one, row_two),
  nrow = 2,
  byrow = TRUE)

matrix_two
```

```
     [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11] [,12] [,13] [,14]
[1,]    1    2    3    4    5    6    7    8    9    10    11    12    13    14
[2,]    1    4    9   16   25   36   49   64   81   100   121   144   169   196

[2,]  5625  5776  5929  6084  6241  6400  6561  6724  6889  7056  7225  7396
     [,87] [,88] [,89] [,90] [,91] [,92] [,93] [,94] [,95] [,96] [,97] [,98]
[1,]    87    88    89    90    91    92    93    94    95    96    97    98
[2,]  7569  7744  7921  8100  8281  8464  8649  8836  9025  9216  9409  9604
     [,99] [,100]
[1,]    99    100
[2,]  9801  10000
```

In the next part, we will discover how knowledge of the way in which a matrix is stored in memory can inform better code choices. To this end, the following function takes an input n and creates an $n \times n$ matrix with random entries.

```
generate_matrix <- function(n){
    return(
        matrix(
            rnorm(n^2),
            nrow=n
        )
    )
}
```

For example:

```
generate_matrix(4)
```

```
           [,1]       [,2]       [,3]        [,4]
[1,] -0.27264758  1.0425960  0.6695323  0.79600535
[2,]  0.38229990 -1.1549060  1.6744849 -0.08194146
[3,]  2.61498754 -1.4661577  1.2576992  0.51569080
[4,]  0.09688861  0.2005935 -1.9915691 -1.18852149
```

Let `M` be a fixed 50×50 matrix

```
M <- generate_matrix(50)
mean(M)
```

```
[1] -0.003025386
```

2. Write a function `row_wise_scan` which scans the entries of `M` one row after another and outputs the number of elements whose value is ≥ 0. You can use the following **starter code**

```
row_wise_scan <- function(M){      #needs to be a function of M
    n <- nrow(M)
    m <- ncol(M)

    count <- 0
    for(i in 1:length(n)){        #start by going through rows
        for(j in 1:length(m)){     #goes through each element in the row
            if(j >= 0){
                count <- count + 1   #updates the count if element j is >= 0
            }
        }
    }

    return(count)
}
```

3. Similarly, write a function `col_wise_scan` which does exactly the same thing but scans the entries of `M` one column after another

```
col_wise_scan <- function(M){   #needs to be a function of M
    count <- 0
    n <- nrow(M)
    m <- ncol(M)

    for(j in 1:length(m)){   #swap order of row_wise_scan, cols first.
      for(i in 1:length(n)){   #goes through each element in the column
        if(i >= 0){
          count <- count + 1   #updates count if element i is >= 0
        }
      }
    }

    return(count)
}
```

You can check if your code is doing what it's supposed to using the function here[1]

[1] If your code is right, the following code should evaluate to be `TRUE`

4. Between `col_wise_scan` and `row_wise_scan`, which function do you expect to take shorter to run? Why?

I wouldn't expect either of these functions to run faster than the other. The matrix M that we are working with is a 50 x 50 matrix, so the amount of time to loop through the columns should be the same amount of time it takes to loop through the rows.

5. Write a function `time_scan` which takes in a method `f` and a matrix `M` and outputs the amount of time taken to run `f(M)`

```
time_scan <- function(f, M){
    initial_time <-  Sys.time()
    f(M)
    final_time <-   Sys.time()

    total_time_taken <- final_time - initial_time
    return(total_time_taken)
}
```

Provide your output to

```
list(
    row_wise_time = time_scan(row_wise_scan, M),
    col_wise_time = time_scan(row_wise_scan, M)
)
```

```
$row_wise_time
Time difference of 0.00632 secs

$col_wise_time
Time difference of 1.28746e-05 secs
```

Which took longer to run?

row_wise_scan took slightly longer to run.

6. Repeat this experiment now when:
    - `M` is a 100×100 matrix
    - `M` is a 1000×1000 matrix
    - `M` is a 5000×5000 matrix

```r
X <- generate_matrix(100)
Y <- generate_matrix(1000)        #just generating the matrices that the
Z <- generate_matrix(5000)        #time_scan function will test

list(
    row_wise_time = time_scan(row_wise_scan, X),     #testing a 100 x 100 matrix
    col_wise_time = time_scan(row_wise_scan, X)
)
```

```
$row_wise_time
Time difference of 1.502037e-05 secs

$col_wise_time
Time difference of 8.106232e-06 secs
```

```r
list(
    row_wise_time = time_scan(row_wise_scan, Y),   #testing a 1000 x 1000 matrix
    col_wise_time = time_scan(row_wise_scan, Y)
)
```

```
$row_wise_time
Time difference of 1.382828e-05 secs

$col_wise_time
Time difference of 7.867813e-06 secs
```

```r
list(
    row_wise_time = time_scan(row_wise_scan, Z),    #testing a 5000 x 5000 matrix
    col_wise_time = time_scan(row_wise_scan, Z)
)
```

```
$row_wise_time
Time difference of 1.215935e-05 secs

$col_wise_time
Time difference of 8.106232e-06 secs
```

What can you conclude?

While the time difference is very minuscule, col_wise_scan() runs slightly faster than row_wise_scan().

Appendix

Print your `R` session information using the following command

```
sessionInfo()
```

```
